

Up to 24V Supply, 4-A Dual Channel High Speed Low Side Driver

FEATURES

- Wide Supply Voltage Range: 4.5V - 24V
- 4A Peak Source Current and 4A Peak Sink Current
- Stackable Output for Higher Driving Capability
- Negative Input Voltage Capability: Down to -5V
- TTL Compatible Input Logic Threshold
- Propagation Delay: 12ns
- Typical Rising and Falling Times: 7ns
- 1ns Typical Delay Matching
- Low Quiescent Current: 50uA
- Output Low When Inputs Floating
- Independent Enable Logic for Each Channel
- Thermal Shutdown Protection: 160°C
- Available in SOP-8 Package

APPLICATIONS

- MOSFET Driver
- IGBT Gate Driver
- Switching Power Supply
- Motor Control, Solar Power

DESCRIPTION

The SCT52240 is a wide supply, dual channel, high speed, low side gate drivers for both power MOSFET, IGBT. Each channel can source and sink 4A peak current along with rail-to-rail output capability. The 24V power supply rail enhances the driver output ringing endurance during the power device transition.

The minimum 12ns input to output propagation delay enables the SCT52240 suitable for high frequency power converter application.

The SCT52240 features wide input hysteresis that is compatible for TTL low voltage logic. The SCT52240 has the capability to handle negative input down to -5V, which increases the input noise immunity.

The SCT52240 has very low quiescent current that reduces the stand by loss in the power converter. The SCT52240 each channel driver adopts non-overlap driver design to avoid the shoot through of output stage. The two channels INA and INB have critical propagation delay matching and artificial dead time implemented in output stage, which enable stackable output available when the system needs higher driving capability.

The SCT52240 features 160°C thermal shut down. The SCT52240 is available in SOP-8 package

Revision 0.8 Preliminary datasheet.

DEVICE ORDER INFORMATION

PART NUMBER	PACKAGE MARKING	PACKAGE DISCRIPTION
SCT52240STD	52240	SOP-8

1) For Tape & Reel, Add Suffix R (e.g. SCT52240STDR).

ABSOLUTE MAXIMUM RATINGS

Over operating free-air temperature unless otherwise noted⁽¹⁾

DESCRIPTION	MIN	MAX	UNIT
ENA, ENB	-0.3	26	V
INA, INB	-5	26	V
OUTA, OUTB	-0.3	26	V
VDD	-0.3	26	V
Operating junction temperature T _J ⁽²⁾	-40	150	°C
Storage temperature T _{STG}	-65	150	°C

PIN CONFIGURATION

Top View: SOP-8pin
Plastic

- (1) Stresses beyond those listed under Absolute Maximum Rating may cause device permanent damage. The device is not guaranteed to function outside of its Recommended Operation Conditions.
- (2) The IC includes over temperature protection to protect the device during overload conditions. Junction temperature will exceed 150°C when over temperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime

PIN FUNCTIONS

NAME	NO.	PIN FUNCTION
ENA	1	Channel A enable logic input, TTL compatible. Floating logic high.
INA	2	Channel A logic input, TTL compatible. Floating logic low.
GND	3	Power ground. Must be soldered directly to ground planes for improved thermal performance and electrical contact.
INB	4	Channel B logic input, TTL compatible. Floating logic low.
OUTB	5	Channel B gate driver output
VDD	6	Power Supply, must be locally bypassed by ceramic cap.
OUTA	7	Channel A gate driver output
ENB	8	Channel B enable logic input, TTL compatible. Floating logic high.

RECOMMENDED OPERATING CONDITIONS

Over operating free-air temperature range unless otherwise noted

PARAMETER	DEFINITION	MIN	MAX	UNIT
V _{DD}	Supply voltage range	4.5	24	V
V _{OUTA} , V _{OUTB}	Output voltage range	4.5	24	V
V _{INA,INB}	Input voltage range	-5	24	
T _J	Operating junction temperature	-40	150	°C

ESD RATINGS

PARAMETER	DEFINITION	MIN	MAX	UNIT
V _{ESD}	Human Body Model (HBM), per ANSI-JEDEC-JS-001-2014 specification, all pins ⁽¹⁾	-2	+2	kV
	Charged Device Model (CDM), per ANSI-JEDEC-JS-002-2014specification, all pins ⁽¹⁾	-0.5	+0.5	kV

(1) HBM and CDM stressing are done in accordance with the ANSI/ESDA/JEDEC JS-001-2014 specification

THERMAL INFORMATION

PARAMETER	THERMAL METRIC	SOP-8L	UNIT
R _{θJA}	Junction to ambient thermal resistance ⁽¹⁾	90	°C/W
R _{θJC}	Junction to case thermal resistance ⁽¹⁾	39	

(1) SCT provides R_{θJA} and R_{θJC} numbers only as reference to estimate junction temperatures of the devices. R_{θJA} and R_{θJC} are not a characteristic of package itself, but of many other system level characteristics such as the design and layout of the printed circuit board (PCB) on which the SCT52240 is mounted, and external environmental factors. The PCB board is a heat sink that is soldered to the leads and thermal pad of the SCT52240. Changing the design or configuration of the PCB board changes the efficiency of the heat sink and therefore the actual R_{θJA} and R_{θJC}.

SCT52240

ELECTRICAL CHARACTERISTICS

V_{DD}=12V, T_J=-40°C~150°C, typical values are tested under 25°C.

FUNCTIONAL BLOCK DIAGRAM

SCT52240

OPERATION

Overview

The SCT52240 is up to 24V wide supply, dual channel, non-invertible, high speed, low side gate drivers for both power MOSFET and IGBT. Each channel can source and sink 4A peak current along with the minimum propagation delay 12ns from input to output. The 1ns delay matching and the stackable output characteristics support higher driving capability demanding in high power converter application. The ability to handle -5V DC input increased the driver input stage noise immunity, the 24V rail-to-rail output improves the SCT52240 output stage robustness during the switching load fast transition. The SCT52240 has flexible input and enable pin configuration, table 1 shows the device output logic truth table.

VDD Power Supply

The SCT52240 operates under a supply voltage range between 4.5V to 24V. For the best high-speed circuit performance, two VDD bypass capacitors in parallel are recommended to prevent noise problems on supply VDD. A 0.1- μ F surface mount ceramic capacitor must be located as close as possible to the VDD to GND pins of the SCT52240. In addition, a larger capacitor (such as 1- μ F or 10 μ F) with relatively low ESR must be connected in parallel, in order to help avoid the unexpected VDD supply glitch. The parallel combination of capacitors presents a low impedance characteristic for the expected current levels and switching frequencies in the application.

Under Voltage Lockout (UVLO)

SCT52240 device Under Voltage Lock Out (UVLO) rising threshold is typically 4.25 V with 350-mV typical hysteresis. When VDD is rising and the level is still below UVLO threshold, this circuit holds the output low regardless of the status of the inputs. The hysteresis prevents output bouncing when low VDD supply voltages have noise from the power supply. The capability to operate at low voltage below 5 V, is especially suited for driving new emerging wide band gap power device like GaN. For example, at power up, the driver output remains low until the VDD voltage reaches the UVLO threshold if enable pin is active or floating. The magnitude of the OUT signal rises with VDD until steady state VDD reached.

The non-inverting operation in Figure 1 shows that the output remains low until the UVLO threshold reached, and then the output is in-phase with the input.

Figure 1 SCT52240 Output Vs VDD

Enable Function

SCT52240 provides independent enable pins ENA and ENB for external control of each channel operation. The enable pins are based on a TTL compatible input-threshold logic that is independent of the supply voltage and are effectively controlled with logic signals from 3.3-V and 5-V microcontrollers. When applying a voltage higher than the high threshold (typical 2.1V), the SCT52240 enables all functions and starts gate driver operation. Driver operation is disabled when ENx voltage falls below its lower threshold (typical 1.1V). The ENx pins are internally pulled up to VDD with 400k pullup resistors. Hence, the ENx pins are left floating or Not Connected (N/C) for standard operation, where the enable feature is not required.

Input Stage

The input of SCT52240 is compatible on TTL input-threshold logic that is independent of the VDD supply voltage. With typically high threshold = 2.1 V and typically low threshold = 1.1 V, the logic level thresholds are conveniently driven with PWM control signals derived from 3.3-V and 5-V digital power-controller devices. Wider hysteresis offers enhanced noise immunity compared to traditional TTL logic implementations, where the hysteresis is typically less than 0.5V. SCT52240 also features tight control of the input pin threshold voltage that ensures stable operation across temperature. The very low input parasitic capacitance on the input pins increases switching speed and reduces the propagation delay.

Output Stage

The SCT52240 output stage features the pull up structure with P-type MOSFET PM1 and N-type MOSFET NM1 in parallel, as shown in Figure 2. PM1 provides the pull up capability when OUT approaches VDD and the NM1 holds off state, which guarantees the driver output is up to VDD rail. The measurable on-resistance R_{OH} in steady state is the conduction resistance of PM1. NM1 provides a narrow instant peak sourcing current up to 4A to eliminate the turn on time and delay. During the output turn on transition, the equivalent hybrid pull on transient resistance is $1.5R_{OL}$, which is much lower than the DC measured R_{OH} .

The N-type MOSFET NM2 composes the output stage pull down structure; the R_{OL} is the DC measurement and represents the pull down impedance. The output stage of SCT52240 provides rail-to-rail operation, and is able to supply 4A sourcing and 4A sinking peak current. The presence of the MOSFET-body diodes also offers low impedance to switching overshoots and undershoots. The outputs of the dual channel drivers are designed to withstand 500-mA reverse current without either damaging to the device or logic malfunction.

Figure 2 SCT52240 Output Stage

Stackable Output

The SCT52240 features 1ns (typical) delay matching between dual channels, which enables dual channel output possible be stacked when the driven power device required higher driving capability. For example, in a Boost Power Factor Correction converter, there are 2 power MOSFET in parallel to support higher power output capability. The two power MOSFET are preferred to be driven by a common gate control signal. By using SCT52240, the OUTA and OUTB can be connected together to provide the higher driving capability, so does the INA and INB. As a result, a single input signal controls the stacked output combination. To support the stackable output, each channel output stage artificially implement up to 5ns dead-time to avoid the possible shoot-through between two channels as shown Figure 3.

Due to the rising and falling threshold mismatch between INA and INB, cautions must be taken when implementing stackable output of OUTA and OUTB together. The maximum mismatch between INA and INB input threshold is up to 10mV (Maximum cross temperature), as a result the allowed minimum slew rate of input logic signal is 2V/us. The following suggestions are recommended when INA and INB connected together and along with the OUTA and OUTB:

1. Apply the fast slew rate dv/dt on input (2 V/us or greater) to avoid the possible shoot-through between OUTA and OUTB output stage.
2. INA and INB must be connected as close to the pins as possible.

Figure 3 SCT52240 Stackable output

The Figure 4 and Figure 5 shows the stackable output with 2V/us input signal.

Figure 4. Driver Switching ON

Figure 5. Driver Switching OFF

Thermal Shutdown

Once the junction temperature in the SCT52240 exceeds 160°C, the thermal sensing circuit stops switching until the junction temperature falling below 135°C, and the device restarts. Thermal shutdown prevents the damage on device during excessive heat and power dissipation condition.

APPLICATION INFORMATION

Typical Application

Figure 6. Dual Channel Driver Typical Application

Driver Power Dissipation

Generally, the power dissipated in the SCT52240 depends on the gate charge required of the power device (Q_g), Switching frequency, and use of external gate resistors. The SCT52240 features very low quiescent currents and internal logic to eliminate any shoot-through in the output driver stage, their effect on the power dissipation within the gate driver is negligible.

For the pure capacitive load, the power loss of each channel in SCT52240 is:

$$P_G = C_{Load} * V_{DD}^2 * f_{SW} \quad (1)$$

Where

- V_{DD} is supply voltage
- C_{Load} is the output capacitance
- f_{SW} is the switching frequency

For the the switching load of power MOSFET, the power loss of each channel in the SCT52240 is shown in equation (2), where charging a capacitor is determined by using the equivalence $Q_g = C_{LOAD}V_{DD}$. The gate charge includes the effects of the input capacitance plus the added charge needed to swing the drain voltage of the power device as it switches between the ON and OFF states. Manufacturers provide specifications that provide the typical and maximum gate charge, in nC, to switch the device under specified conditions.

$$P_G = Q_g * V_{DD} * f_{SW} \quad (2)$$

Where

- Q_g is the gate charge of the power device
- f_{SW} is the switching frequency
- V_{DD} is the supply voltage

If R_G applied between driver and gate of power device to slow down the power device transition, the power dissipation of the driver shows as below:

$$P_G = \frac{1}{2} * Q_g * V_{DD} * f_{SW} * \left(\frac{R_{OL}}{R_{OL} + R_G} + \frac{R_{OH}}{R_{OH} + R_G} \right) \quad (3)$$

Where

- R_{OH} is the equivalent pull up resistance of SCT52240
- R_{OL} is the pull down resistance of SCT52240
- R_G is the gate resistance between driver output and gate of power device.

Layout Guideline

The SCT52240 provides the 4A output driving current and features very short rising and falling time at the power devices gate. The high di/dt causes driver output unexpected ringing when the driver output loop is not designed well. The regulator could suffer from malfunction and EMI noise problems if the power device gate has serious ringing. Below are the layout recommendations with using SCT52240 and Figure 13 is the layout example.

Put the SCT52240 as close as possible to the power device to minimize the gate driving loop including the driver output and power device gate. The power supply decoupling capacitors needs to be close to the VDD pin and GND pin to reduce the supply ripple. For the output stackable application, the driver input loop of two-channel input must be strictly symmetrical to ensure the input propagation delay is the same.

Star-point grounding is recommend to minimize noise coupling from one current loop to the other. The GND of the driver connects to the other circuit nodes such as source of power MOSFET or ground of PWM controller at single point. The connected paths must be as short as possible to reduce parasitic inductance. A ground plane is to provide noise shielding and thermal dissipation as well.

Figure 13. SCT52240 PCB Layout Example

Thermal Considerations

The maximum IC junction temperature should be restricted to 150°C under normal operating conditions. Calculate the maximum allowable dissipation, $P_{D(max)}$, and keep the actual power dissipation less than or equal to $P_{D(max)}$. The maximum-power-dissipation limit is determined using Equation (4).

$$P_{D(MAX)} = \frac{150 - T_A}{R_{\theta JA}} \quad (4)$$

where

- T_A is the maximum ambient temperature for the application.
- $R_{\theta JA}$ is the junction-to-ambient thermal resistance given in the Thermal Information table.

The real junction-to-ambient thermal resistance $R_{\theta JA}$ of the package greatly depends on the PCB type, layout, and environmental factor. Soldering the ground pin to a large ground plate enhance the thermal performance. Using more vias connects the ground plane on the top layer and bottom layer around the IC without solder mask also improves the thermal capability.
